

## **Why is Cyber Security a Problem?**

You've heard the news stories about credit card numbers being stolen and email viruses spreading. Maybe you've even been a victim yourself. One of the best defenses is understanding the risks, what some of the basic terms mean, and what you can do to protect yourself against them.

## **What is cyber security?**

It seems everything relies on computers and the Internet now – communication (email, cellphones), entertainment (digital cable, mp3s), transportation (car engine systems, airplane navigation), shopping (online stores, credit cards), medicine (equipment, medical records), and the list goes on. How much of your daily life relies on computers? How much of your personal information is stored either on your own computer or on someone else's system?

Cyber security involves protecting that information by preventing, detecting, and responding to attacks.

## **What are the risks?**

There are many risks, some more serious than others. Among these dangers are viruses erasing your entire system, someone breaking into your system and altering files, someone using your computer to attack others, or someone stealing your credit card information and making unauthorized purchases. Unfortunately, there's no 100% guarantee even with the best precautions some of these things won't happen to you, but there are steps you can take to minimize the chances.

## **What can you do?**

The first step in protecting yourself is to recognize the risks and become familiar with some of the terminology associated with them.

*Hacker, attacker, or intruder* - These terms are applied to the people who seek to exploit weaknesses in software and computer systems for their own gain. Although their intentions are sometimes fairly benign and motivated solely by curiosity, their actions are typically in violation of the intended use of the systems they are exploiting. The results can range from mere mischief (creating a virus with no intentionally negative impact) to malicious activity (stealing or altering information).

*Malicious code* - This category includes code such as viruses, worms, and Trojan horses. Although some people use these terms interchangeably, they have unique characteristics.

Virus - This type of malicious code requires you to actually do something before it infects your computer. This action could be opening an email attachment or going to a particular web page.

Worm - Worms propagate without user intervention. They typically start by exploiting a software vulnerability (a flaw allowing the software's intended security policy to be violated), then once the victim computer has been infected, the worm will attempt to find and infect other computers. Similar to viruses, worms can propagate via email, web sites, or network-based software. The automated self-propagation of worms distinguishes them from viruses.

Trojan horse - A Trojan horse program is software claiming to be one thing while in fact doing something different behind the scenes. For example, a program claiming it will speed up your computer may actually be sending confidential information to a remote intruder.
